Distributed Denial-of-Service Open Threat Signaling (DOTS) Data Channel  
~~draft-ietf-dots-data-channel-11~~  
draft-ietf-dots-data-channel-12

## Abstract

The document specifies a Distributed Denial-of-Service Open Threat Signaling (DOTS) data channel used for bulk exchange of data ~~not that~~ **cannot** easily or appropriately communicated through the DOTS signal channel under attack conditions.

This is a companion document to the DOTS signal channel specification.

## Editorial Note (To be removed by RFC Editor)

Please update these statements with the RFC number to be assigned to this document:

- o "This version of this YANG module is part of RFC XXXX;"
- o "RFC XXXX: Distributed Denial-of-Service Open Threat Signaling (DOTS) Data Channel";
- o reference: RFC XXXX

## Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on June ~~21~~, 23, 2018.

## 1. Introduction

A distributed denial-of-service (DDoS) attack is an attempt to make machines or network resources unavailable to their intended users. In most cases, sufficient scale can be achieved by compromising enough end-hosts and using those infected hosts to perpetrate and amplify the attack. The victim ~~in of~~ such attack can be an application server, a router, a firewall, an entire network, etc.

As discussed in [I-D.ietf-dots-requirements], the lack of a common method to coordinate a real-time response among involved actors and network domains inhibits the speed and effectiveness of DDoS attack mitigation. From that standpoint, DDoS Open Threat Signaling (DOTS) [I-D.ietf-dots-architecture] defines an architecture ~~enabling that allows a DOTS client to send requests to a DOTS server for DDoS attack mitigation, reducing attack impact, and mitigation. The DOTS approach is thus meant to minimize the impact of DDoS attacks, thereby contributing to the enforcement of more efficient defensive if not proactive security strategies.~~ To that aim, DOTS defines two channels: the signal and the data channels (Figure 1).

Figure 1: DOTS Channels

The DOTS signal channel is used to ~~convey that~~ carry information about a device or a network (or a part thereof) that is under a DDoS ~~attack~~ attack. Such information is sent by a DOTS client to an upstream DOTS server so that appropriate mitigation actions are undertaken on ~~the suspect traffic,~~ traffic deemed suspicious. The DOTS signal channel is further elaborated in [I-D.ietf-dots-signal-channel].

The

As for the DOTS data ~~channel~~ channel, it is used for infrequent bulk data exchange between DOTS agents ~~in the aim~~ to significantly ~~augment attack~~ improve the coordination of all the parties involved in the response ~~coordination, to the attack.~~ Section 2 of [I-D.ietf-dots-architecture] identifies mentions that the DOTS data channel is used to perform the following tasks:

- o Creating identifiers, such as names or aliases, for resources for which mitigation may be requested.

A DOTS client may submit to its DOTS server a collection of

prefixes which it would like to refer to by an alias when requesting mitigation. The DOTS server can respond to this request with either a success or failure response (see Section 2 in [I-D.ietf-dots-architecture]).

Refer to Section 6 for more details.

- o Filter management, which enables a DOTS client to request the installation or ~~removal~~ **withdrawal** of traffic filters, dropping or rate-limiting unwanted traffic, and permitting white-listed traffic.

Sample use cases for populating black- or white-list filtering rules are detailed hereafter:

- \* If a network resource (DOTS client) detects a potential DDoS attack from a set of IP addresses, the DOTS client informs its servicing DOTS gateway of all suspect IP addresses that need to be blocked or black-listed for further investigation. The DOTS client could also specify a list of protocols and port numbers in the black-list rule.

The DOTS gateway ~~in-turn~~ **then** propagates the black-listed IP addresses to a DOTS server which will undertake appropriate actions so that traffic ~~from~~ **originated by** these IP addresses to the target network (specified by the DOTS client) is blocked.

- \* A network, that has partner sites from which only legitimate traffic arrives, may want to ensure that the traffic from these sites is ~~not-penalized-during~~ **protected from** DDoS attacks. The DOTS client uses the DOTS data channel to convey the white-listed IP prefixes of the partner sites to its DOTS server.

The DOTS server uses this information to white-list flows ~~from~~ **originated by** such IP prefixes ~~reaching and which reach~~ the network.

Refer to Section 7 for more details.

## 2. Notational Conventions and Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

The reader should be familiar with the terms defined in [I-D.ietf-dots-architecture].

The terminology for describing YANG data modules is defined in [RFC7950]. The meaning of the symbols in tree diagrams is defined in [I-D.ietf-netmod-yang-tree-diagrams].

For **the sake of** simplicity, all of the examples in this document use "/restconf" as the discovered RESTCONF API root path. Many protocol header lines and message-body text within examples throughout the document are split into multiple lines for display purposes only. When a line ends with backslash ('\') as the last character, the line is wrapped for display purposes. It is to be considered to be joined to the next line by deleting the backslash, the following line break, and the leading whitespace of the next line.

## 3. DOTS Data Channel: Design Overview

Unlike the DOTS signal channel [I-D.ietf-dots-signal-channel], which must ~~operate-nominally~~ **remain operational** even when confronted with signal degradation due to packets loss, the DOTS data channel is not expected to be ~~constructed-to-deal-with~~ **fully operational at all times, especially when a DDoS attack conditions- is underway**. The requirements for a DOTS data channel protocol are documented in [I-D.ietf-dots-requirements].

This specification does not require an order of ~~contact-nor-the-time~~ **interval-between** DOTS signal and data channel ~~creations-~~ **creations nor mandates a time interval between them**. These considerations are implementation- and deployment-specific.

As the primary function of the data channel is data exchange, a reliable transport **mode** is required in order for DOTS agents to detect data delivery success or failure. This document uses RESTCONF [RFC8040] over TLS [RFC5246] over TCP as the DOTS data channel

protocol (Figure 2).

Note: RESTCONF is a protocol based on HTTP [RFC7230] to provide CRUD (create, read, update, delete) operations on a conceptual datastore containing YANG data. Concretely, RESTCONF is used for configuring data defined in YANG version 1 [RFC6020] or YANG version 1.1 [RFC7950], using the datastore concepts defined in the Network Configuration Protocol (NETCONF) [RFC6241]. RESTCONF combines the simplicity of the HTTP protocol with the predictability and automation potential of a schema-driven API. RESTCONF offers a simple subset of NETCONF functionality and provides a simplified interface using REST-like API which addresses the needs of the DOTS data channel and hence an optimal choice.

Figure 2: Abstract Layering of DOTS Data Channel over RESTCONF over TLS

The HTTP POST, PUT, PATCH, and DELETE methods are used to edit data resources represented by DOTS data channel YANG data modules. These basic edit operations allow the DOTS data channel running configuration to be altered by a DOTS client.

DOTS data channel configuration ~~data and information as well as~~ state ~~data information~~ can be retrieved with the GET method. An HTTP ~~status-line~~ ~~status-line~~ header field is returned for each request to report success or failure for RESTCONF operations (Section 5.4 of [RFC8040]).

The DOTS client performs the root resource discovery procedure discussed in Section 3.1 of [RFC8040] to determine the root of the RESTCONF API. After discovering the RESTCONF API root, the DOTS client uses this value as the initial part of the path in the request URI, in any subsequent request to the DOTS server. The DOTS server may support ~~the~~ retrieval of the YANG modules it supports (Section 3.7 in ~~[RFC8040]], for [RFC8040]]~~. For example, a DOTS client may use RESTCONF to retrieve the ~~company-proprietary~~ ~~vendor-specific~~ YANG modules supported by the DOTS server.

JavaScript Object Notation (JSON) [RFC7159] payload is used to propagate ~~the DOTS~~ data channel specific payload messages that ~~convey~~ ~~carry~~ request parameters and response ~~information~~ ~~information~~, such as errors. This specification uses the encoding rules defined in [RFC7951] for representing DOTS data channel configuration data ~~defined~~ using YANG (Section 5) as JSON text.

A DOTS client registers itself to its DOTS server(s) in order to set up DOTS data ~~channel-related~~ ~~channel-related~~ configuration data and receive state data (i.e., non-configuration data) from the DOTS server(s).

A single DOTS data channel between DOTS agents can be used to exchange multiple requests and multiple responses. To reduce DOTS client and DOTS server workload, DOTS client SHOULD re-use the same TLS session. While the communication to the DOTS server is quiescent, the DOTS client MAY probe the server to ensure it has maintained cryptographic state. Such probes can also keep alive firewall and/or NAT bindings. A TLS heartbeat [RFC6520] verifies ~~that~~ the DOTS server still has TLS state by returning a TLS message.

In deployments where one or more translators (e.g., NAT44, NAT64, NPTv6) are enabled between the client's network and the DOTS server, DOTS data channel messages forwarded to a DOTS server must not include internal IP addresses/prefixes and/or port numbers; external addresses/prefixes and/or port numbers as assigned by the translator must be used instead. This document does not make any recommendation about possible translator discovery mechanisms. The following are

some (non-exhaustive) deployment examples that may be considered:

- o Port Control Protocol (PCP) [RFC6887] or Session Traversal Utilities for NAT (STUN) [RFC5389] may be used to retrieve the external addresses/prefixes and/or port numbers. Information retrieved by means of PCP or STUN will be used to feed the DOTS data channel messages that will be sent to a DOTS server.
- o A DOTS gateway may be co-located with the translator. The DOTS gateway will need to update the DOTS messages, based upon the local translator's binding table.

When a DOTS gateway is involved in DOTS data channel exchanges, the same considerations for manipulating **the** 'client-identifier' parameter as specified in [I-D.ietf-dots-signal-channel] MUST be followed by DOTS agents. This specification includes examples to illustrate sample messages without any 'client-identifier' parameter, messages with **the** 'client-identifier' parameter ~~having one single value,~~ **being single-valued,** and messages with 'client-identifier' parameter listing multiple values.

A DOTS server may detect conflicting filtering requests from the same or distinct DOTS clients which belong to the same domain. For example, a DOTS client would request to blacklist a prefix, while another DOTS client would request to whitelist that same prefix. It is out of scope of this specification to recommend the behavior to follow for handling conflicting requests (e.g., reject all, reject the new request, notify an administrator for validation). DOTS servers SHOULD support a configuration parameter to indicate the behavior to follow when a conflict is detected. Section 7.1 specifies the behavior when no instruction is supplied to a DOTS server.

#### 4. DOTS Server(s) Discovery

This document assumes that DOTS clients are provisioned with the reachability information of their DOTS server(s) using a variety of means (e.g., local configuration, or dynamic means such as DHCP).

~~These~~

**The specification of such** means are out of scope of this document.

Likewise, it is out of scope of this document to specify the behavior to follow by a DOTS client to place its requests (e.g., contact all servers, select one server among the list) when multiple DOTS servers are provisioned.

#### 5. DOTS Data Channel YANG Module

##### 5.1. Identifier YANG Tree Structure

The YANG module (ietf-dots-data-channel) allows to create identifiers, such as names or aliases, for resources for which mitigation may be requested. Such identifiers may be used in subsequent DOTS signal channel exchanges to refer more efficiently to the resources under attack. The tree structure for DOTS identifiers is as follows:

```

+--rw identifier
  +--rw client-identifier*   binary
  +--rw alias* [alias-name]
    +--rw alias-name         string
    +--rw target-prefix*      inet:ip-prefix
    +--rw target-port-range* [lower-port upper-port]
      | +--rw lower-port      inet:port-number
      | +--rw upper-port      inet:port-number
    +--rw target-protocol*    uint8
    +--rw target-fqdn*         inet:domain-name
    +--rw target-uri*          inet:uri

```

This structure is aligned with [I-D.ietf-dots-signal-channel].

##### 5.2. Filter YANG Tree Structure

This document augments the Access Control List (ACL) YANG module [I-D.ietf-netmod-acl-model] for managing DOTS filtering rules. The notion of ACL is explained in Section 1 of [I-D.ietf-netmod-acl-model].

Examples of ACL management in a DOTS context include, but not limited to:

- o Black-list management, which enables a DOTS client to inform a DOTS server about sources from which traffic should be ~~suppressed~~ discarded.
- o White-list management, which enables a DOTS client to inform a DOTS server about sources from which traffic should always be accepted.
- o Filter management, which enables a DOTS client to request the installation or ~~removal~~ withdrawal of traffic filters, dropping or rate-limiting unwanted traffic and permitting white-listed traffic.

This document defines the DOTS Data Channel YANG to augment the "ietf-access-control-list" module to support filters based on the client identifier (client-identifier), to support rate-limit action (rate-limit), and to handle fragmented packets (fragments).

Filtering fragments adds an additional layer of protection against a DoS attack that uses ~~only~~ non-initial ~~fragments~~ fragments only. When there is only Layer 3 information in the ACL entry and the fragments keyword is present, for non-initial fragments matching the ACL entry, the deny or permit action associated with the ACL entry will be ~~enforced-and~~ ~~for~~ enforced. For initial or non-fragment matching the ACL entry, the next ACL entry will be processed. When there is both Layer 3 and Layer 4 information in the ACL entry and the fragments keyword is present, the ACL action is conservative for both permit and deny actions. The actions are conservative to not accidentally deny a fragmented portion of a flow because the fragments do not contain sufficient information to match all of the filter attributes. In the deny action case, instead of denying a non-initial fragment, the next ACL entry is processed. In the permit case, it is assumed that the Layer 4 information in the non-initial fragment, if available, matches the Layer 4 information in the ACL entry.

The tree structure for DOTS filtering rules is as follows:

```
augment /ietf-acl:access-lists:
  +--rw client-identifier*   binary
augment /ietf-acl:access-lists/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:actions:
  +--rw rate-limit?         decimal64
augment /ietf-acl:access-lists/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:matches/ietf-acl:ipv4-acl:
  +--rw fragments?         empty
augment /ietf-acl:access-lists/ietf-acl:acl/ietf-acl:aces/ietf-acl:ace/ietf-acl:matches/ietf-acl:ipv6-acl:
  +--rw fragments?         empty
augment /ietf-acl:access-lists:
  +--rw dots-acl-order
    +--rw acl-set* [set-name type]
      +--rw set-name      -> /ietf-acl:access-lists/acl/acl-name
      +--rw type           -> /ietf-acl:access-lists/acl/acl-type
```

### 5.3. YANG Module

```
<CODE BEGINS> file "ietf-dots-data-channel@2017-12-18.yang"

## 6. DOTS Identifiers

### 6.1. Create Identifiers

A POST request is used to create identifiers, such as names or aliases, for resources for which a mitigation may be requested. Such identifiers may be used in subsequent DOTS signal channel exchanges to refer more efficiently to the resources under attack (Figure 3).

DOTS clients within the same domain can create different aliases for the same resource.

```

POST /restconf/data/ietf-dots-data-channel HTTP/1.1
Host: {host}:{port}
Content-Type: "application/yang-data+json"
{

```

```

"ietf-dots-data-channel:identifier": {
  "client-identifier": [
    "string"
  ],
  "alias": [
    {
      "alias-name": "string",
      "target-prefix": [
        "string"
      ],
      "target-port-range": [
        {
          "lower-port": integer,
          "upper-port": integer
        }
      ],
      "target-protocol": [
        integer
      ],
      "target-fqdn": [
        "string"
      ],
      "target-uri": [
        "string"
      ]
    }
  ]
}

```

Figure 3: POST to create identifiers

The parameters are described below:

**client-identifier:** This attribute has the same meaning, syntax, and processing rules as the 'client-identifier' attribute defined in [I-D.ietf-dots-signal-channel].

This is an optional attribute.

**alias-name:** Name of the alias.

This is a mandatory attribute.

**target-prefix:** Prefixes are separated by commas. Prefixes are represented using Classless Inter-domain Routing (CIDR) notation [RFC4632]. As a reminder, the prefix length must be less than or equal to 32 (resp. 128) for IPv4 (resp. IPv6).

This is an optional attribute.

**target-port-range:** A range of port numbers.

The port range is defined by two bounds, a lower port number (lower-port) and an upper port number (upper-port).

When only 'lower-port' is present, it represents a single port number.

For TCP, UDP, Stream Control Transmission Protocol (SCTP) [RFC4960], or Datagram Congestion Control Protocol (DCCP) [RFC4340], the range of port numbers can be, for example, 1024-65535.

This is an optional attribute.

**target-protocol:** A list of protocols. Values are taken from the IANA protocol registry [proto\_numbers].

The value '0' has a special meaning for 'all protocols'.

This is an optional attribute.

**target-fqdn:** A list of Fully Qualified Domain Names (FQDNs). An FQDN is the full name of a resource, rather than just its hostname. For example, "venera" is a hostname, and "venera.isi.edu" is an FQDN.

This is an optional attribute.

target-uri: A list of Uniform Resource Identifiers (URIs) [RFC3986].

This is an optional attribute.

In the POST ~~request~~ **request**, at least one of the ~~attributes~~ **attributes** 'target-prefix' or ~~'target-fqdn'~~ **'target-fqdn'** or 'target-uri' **attributes** MUST be present. DOTS agents can safely ignore Vendor-Specific parameters they don't understand.

Figure 4 shows a POST request to create alias called "https1" for HTTPS servers with IP addresses 2001:db8:6401::1 and 2001:db8:6401::2 listening on port 443.

```
POST /restconf/data/ietf-dots-data-channel HTTP/1.1
Host: www.example.com
Content-Type: "application/yang-data+json"
{
  "ietf-dots-data-channel:identifier": {
    "alias": [
      {
        "alias-name": "https1",
        "target-protocol": [
          6
        ],
        "target-prefix": [
          "2001:db8:6401::1/128",
          "2001:db8:6401::2/128"
        ],
        "target-port-range": [
          {
            "lower-port": 443
          }
        ]
      }
    ]
  }
}
```

Figure 4: POST to create identifiers

The DOTS server indicates the result of processing the POST request using status-line codes. Status codes in the range "2xx" codes are success, "4xx" codes are some sort of invalid requests and "5xx" codes are returned if the DOTS server has erred or ~~it~~ is incapable of accepting the alias.

"201 Created" status-line is returned in the response if the DOTS server has accepted the alias.

If the request is missing one or more mandatory ~~attributes~~ **attributes**, or if the request contains invalid or unknown parameters, then "400 Bad Request" status-line MUST be returned in the response. The HTTP response will include the JSON body received in the request.

A DOTS client MAY use the PUT request (Section 4.5 in [RFC8040]) to create or modify the aliases in the DOTS server.

## 6.2. Retrieve Installed Identifiers

A GET request is used to retrieve one or all installed identifiers by a DOTS client from a DOTS server (Section 3.3.1 in [RFC8040]). If no 'alias-name' parameter is included in the request, this is an indication **that** the request is about retrieving all identifiers instantiated by the DOTS client.

Figure 5 shows an example to retrieve all the identifiers that were instantiated by the DOTS client. The content parameter and its permitted values are defined in Section 4.8.1 of [RFC8040].

```
GET /restconf/data/ietf-dots-data-channel:identifier\
/client-identifier=dz6pHjaADkaFTbjr0JGBpw?
content=config HTTP/1.1
Host: {host}:{port}
Accept: application/yang-data+json
```

Figure 5: GET to retrieve all the installed identifiers

Figure 6 shows an example of response message body that includes all the identifiers that are maintained by the DOTS server for **the** DOTS client identified by the 'client-identifier' parameter.

```
{
  "ietf-dots-data-channel:identifier": {
    "client-identifier": [
      "dz6pHjaADkaFTbjr0JGBpw"
    ],
    "alias": [
      {
        "alias-name": "Server1",
        "traffic-protocol": [
          6
        ],
        "target-prefix": [
          "2001:db8:6401::1/128",
          "2001:db8:6401::2/128"
        ],
        "target-port-range": [
          {
            "lower-port": 443
          }
        ]
      },
      {
        "alias-name": "Server2",
        "target-protocol": [
          6
        ],
        "target-prefix": [
          "2001:db8:6401::10/128",
          "2001:db8:6401::20/128"
        ],
        "target-port-range": [
          {
            "lower-port": 80
          }
        ]
      }
    ]
  }
}
```

Figure 6: Response body

If **the** 'alias-name' parameter is included in the request, but the DOTS server does not find that alias name in its configuration data, it MUST respond with a "404 Not Found" status-line.

### 6.3. Delete Identifiers

A DELETE request is used to delete identifiers maintained by a DOTS server.

In RESTCONF, URI-encoded path expressions are used. A RESTCONF data resource identifier is encoded from left to right, starting with the top-level data node, according to the 'api-path' rule defined in Section 3.5.3.1 of [RFC8040]. The data node in the path expression is a YANG list node and MUST be encoded according to the rules defined in Section 3.5.1 of [RFC8040].

If the DOTS server does not find the alias name conveyed in the DELETE request in its configuration data, it MUST respond with a "404 Not Found" status-line.

The DOTS server successfully acknowledges a DOTS client's request to remove the identifier using "204 No Content" status-line in the response.

Figure 7 shows an example of a request to delete an alias.

```
DELETE /restconf/data/ietf-dots-data-channel:identifier\
/client-identifier=dz6pHjaADkaFTbjr0JGBpw,\
iAYmCNPmrYoKqzgFMiobw/alias-name=Server1 HTTP/1.1
Host: {host}:{port}
```

Figure 7: DELETE an identifier

## 7. DOTS Filtering Rules

The DOTS server either receives the filtering rules directly from the DOTS client or via a DOTS gateway.

If the DOTS client signals the filtering rules via a DOTS gateway, the DOTS gateway **validates** first **if verifies that** the DOTS client is authorized to signal the filtering rules. If the client is authorized, it propagates the rules to the DOTS server. Likewise, the DOTS server **validates-if verifies that** the DOTS gateway is authorized to signal the filtering rules. To create or purge filters, the DOTS client sends HTTP requests to its DOTS gateway. The DOTS gateway validates the rules in the requests and proxies the requests containing the filtering rules to a DOTS server. When the DOTS gateway receives the associated HTTP response from the DOTS server, it propagates the response back to the DOTS client.

The following sub-sections define means for a DOTS client to configure filtering rules on a DOTS server.

### 7.1. Install Filtering Rules

A POST request is used to push filtering rules to a DOTS server.

Figure 8 shows a POST request example to block traffic from ~~192.0.2.0/24~~, **192.0.2.0/24** and destined to 198.51.100.0/24. The ACL JSON configuration for the filtering rule is generated using the ACL YANG module (Section 4.3 of [I-D.ietf-netmod-acl-model]).

```
POST /restconf/data/ietf-dots-data-channel HTTP/1.1
Host: www.example.com
Content-Type: "application/yang-data+json"
{
  "ietf-dots-data-channel:access-lists": {
    "client-identifier": [
      "dz6pHjaADkaFTbjr0JGBpw"
    ],
    "acl": [
      {
        "acl-name": "sample-ipv4-acl",
        "acl-type": "ipv4-acl",
        "aces": {
          "ace": [
            {
              "rule-name": "rule1",
              "matches": {
                "ipv4-acl": {
                  "source-ipv4-network": "192.0.2.0/24",
                  "destination-ipv4-network": "198.51.100.0/24"
                }
              },
              "actions": {
                "forwarding": "drop"
              }
            }
          ]
        }
      }
    ]
  }
}
```

Figure 8: POST to install filtering rules

The parameters defined in [I-D.ietf-netmod-acl-model] are discussed below:

**acl-name**: The name of **the** access-list. This is a mandatory attribute.

**acl-type**: Indicates the primary intended type of match criteria (e.g., IPv4, IPv6). This is a mandatory attribute.

protocol: Internet Protocol numbers. This is an optional attribute.

source-ipv4-network: The source IPv4 prefix. This is an optional attribute.

destination-ipv4-network: The destination IPv4 prefix. This is an optional attribute.

actions: Actions in the forwarding ACL category can be "drop" or "accept" or "rate-limit". The "accept" action is used to ~~white-list~~ **white-list** traffic. The "drop" action is used to black-list traffic. ~~"rate-limit"~~  
 The "rate-limit" action is used to rate-limit traffic, the allowed traffic rate is represented in bytes per second indicated in IEEE floating point format [IEEE.754.1985]. This is an optional attribute.

The DOTS server indicates the result of processing the POST request using the status-line header. "2xx" codes are success, 4xx codes are some sort of invalid requests, and 5xx codes are returned if the DOTS server has erred or ~~it~~ is incapable of configuring the filtering rules. Concretely, "201 Created" status-line MUST be returned in the response if the DOTS server has accepted the filtering rules. If the request is missing one or more mandatory attributes or contains invalid or unknown parameters, then "400 Bad Request" status-line MUST be returned in the response.

If the request is conflicting with an existing filtering, the DOTS server returns "409 Conflict" status-line to the requesting DOTS client. The error-tag "invalid-value" is used in this case.

The "insert" query parameter discussed in Section 4.8.5 of [RFC8040] MAY be used to specify how ~~a-ACE~~ **an Access Control Entry (ACE)** is inserted within an ACL and how a ACL is inserted within an ACL list.

The DOTS client MAY use the PUT request to create or modify the filtering rules in the DOTS server.

## 7.2. Retrieve Installed Filtering Rules

The DOTS client periodically queries the DOTS server to check the counters for installed filtering rules. A GET request is used to retrieve filtering rules from a DOTS server.

If the DOTS server does not find the access list name and access list type conveyed in the GET request in its configuration data, it responds with a "404 Not Found" status-line.

Figure 9 shows how to retrieve all the filtering rules programmed by the DOTS client and the number of matches for the installed filtering rules.

```
GET /restconf/data/ietf-dots-data-channel:access-lists\
  /client-identifier=dz6pHjaADkaFTbjr0JGBpw?\
  content=all HTTP/1.1
Host: {host}:{port}
Accept: application/yang-data+json
```

Figure 9: GET to retrieve the configuration data and state data for the filtering rules

## 7.3. Remove Filtering Rules

A DELETE request is used to delete filtering rules from a DOTS server.

If the DOTS server does not find the access list name and access list type ~~conveyed~~ **carried** in the DELETE request in its configuration data, ~~then it then~~ responds with a "404 Not Found" status-line. The DOTS server successfully acknowledges a DOTS client's request to withdraw the filtering rules using "204 No Content" status-line, and removes the filtering rules ~~as soon as possible.~~ **accordingly.**

Figure 10 shows an example of a request to remove the IPv4 ACL named "sample-ipv4-acl". This request is being relayed by a DOTS gateway as hinted by the presence of the 'client-identifier' parameter.

```
DELETE /restconf/data/ietf-dots-data-channel:access-lists\
/client-identifier=dz6pHjaADkaFTbjr0JGBpw\
/acl-name=sample-ipv4-acl&\
acl-type=ipv4-acl HTTP/1.1
Host: {host}:{port}
```

Figure 10: DELETE to remove the filtering rules

## 8. IANA Considerations

### 8.1. DOTS Data Channel JSON Attribute Mappings Registry

The document requests IANA to create a new registry, entitled "DOTS Data Channel JSON Attribute Mappings Registry". The structure of this registry is provided in Section 8.1.1.

The registry is initially populated with the values in Section 8.1.2.

Values from that registry MUST be assigned via Expert Review [RFC8126].

#### 8.1.1. Registration Template

JSON Attribute:  
JSON attribute name.

Description:  
Brief description of the attribute.

Change Controller:  
For Standards Track RFCs, list the "IESG". For others, give the name of the responsible party. Other details (e.g., postal address, email address, home page URI) may also be included.

Specification Document(s):  
Reference to the document or documents that specify the parameter, preferably including URIs that can be used to retrieve copies of the documents. An indication of the relevant sections may also be included but is not required.

#### 8.1.2. Initial Registry Contents

- o JSON Attribute: "client-identifier"
- o Description: Client identifier.
- o Change Controller: IESG
- o Specification Document(s): this document
  
- o JSON Attribute: "alias-name"
- o Description: Name of alias.
- o Change Controller: IESG
- o Specification Document(s): this document
  
- o JSON Attribute: "target-protocol"
- o Description: Internet protocol numbers.
- o Change Controller: IESG
- o Specification Document(s): this document
- o JSON Attribute: "target-port-range"
- o Description: The port range, lower-port for lower port number and upper-port for upper port number. For TCP, UDP, SCTP, or DCCP: a range of ports can be, e.g., 80 to 8080.
- o Change Controller: IESG
- o Specification Document(s): this document
  
- o JSON Attribute: "lower-port"
- o Description: Lower port number for the port range.
- o Change Controller: IESG
- o Specification Document(s): this document
  
- o JSON Attribute: "upper-port"
- o Description: Upper port number for the port range.
- o Change Controller: IESG
- o Specification Document(s): this document
  
- o JSON Attribute: "target-prefix"
- o Description: IP prefix
- o Change Controller: IESG
- o Specification Document(s): this document

- o JSON Attribute: "target-fqdn"
- o Description: Fully Qualified Domain Name, is the full name of a system, rather than just its hostname. For example, "venera" is a hostname, and "venera.isi.edu" is an FQDN.
- o Change Controller: IESG
- o Specification Document(s): this document
  
- o JSON Attribute: "target-uri"
- o Description: Uniform Resource Identifier (URI).
- o Change Controller: IESG
- o Specification Document(s): this document

## 8.2. YANG Module

This document requests IANA to register the following URI in the "IETF XML Registry" [RFC3688]:

```
URI: urn:ietf:params:xml:ns:yang:ietf-dots-data-channel
Registrant Contact: The IESG.
XML: N/A; the requested URI is an XML namespace.
```

This document requests IANA to register the following YANG module in the "YANG Module Names" registry [RFC7950].

```
name: ietf-dots-data-channel
namespace: urn:ietf:params:xml:ns:yang:ietf-dots-data-channel
prefix: data-channel
reference: RFC XXXX
```

## 9. Contributors

The following individuals have contributed to this document:

Dan Wing

Email: [dwing-ietf@fuggles.com](mailto:dwing-ietf@fuggles.com)

## 10. Security Considerations

RESTCONF security considerations are discussed in [RFC8040]. In particular, DOTS agents MUST follow the security recommendations in Sections 2 and 12 of [RFC8040] and **support** the mutual authentication TLS profile discussed in Section 7.1 of [I-D.ietf-dots-signal-channel].

Authenticated encryption MUST be used for data confidentiality and message integrity. The interaction between the DOTS agents requires Transport Layer Security (TLS) with a cipher suite offering confidentiality protection and the guidance given in [RFC7525] MUST be followed to avoid attacks on TLS.

An attacker may be able to inject RST packets, bogus application segments, etc., regardless of whether TLS authentication is used. Because the application data is TLS protected, this will not result in the application receiving bogus data, but it will constitute a DoS on the connection. This attack can be countered by using TCP-AO [RFC5925]. If TCP-AO is used, then any bogus packets injected by an attacker will be rejected by the TCP-AO integrity check and therefore will never reach the TLS layer.

In order to prevent leaking internal information outside a client-domain, client-side DOTS gateways SHOULD NOT reveal the identity of internal DOTS clients (client-identifier) unless explicitly configured to do so.

Special care should be taken in order to ensure that the activation of the proposed mechanism ~~won't have an impact on~~ **will not affect** the stability of the network (including connectivity and services delivered over that network).

All data nodes defined in the YANG module which can be created, modified, and deleted (i.e., config true, which is the default) are considered sensitive. Write operations applied to these data nodes without proper protection can negatively affect network operations. Appropriate security measures are recommended to prevent illegitimate users from invoking DOTS data channel primitives. Nevertheless, an attacker who ~~is able to~~ **can** access ~~to~~ a DOTS client ~~can undertake~~ **is technically capable of launching** various attacks, such as:

- o Set an arbitrarily low ~~rate-limit that~~ **rate-limit**, which may ~~lead-to-discarding~~ **prevent** legitimate traffic ~~to-be from being~~ forwarded (rate-limit).
- o Set an arbitrarily high ~~rate-limit that~~ **rate-limit**, which may lead to **allowing the forwarding of** illegitimate DDoS traffic ~~to-be-forwarded or the overload of the device that embeds the DOTS client~~ (rate-limit).
- o Communicate invalid aliases to the server ~~(alias)-that~~ **(alias)**, which will ~~lead to~~ **cause the failure to-associate of associating** both data and signal channels.
- o Set invalid ACL ~~entries-that~~ **entries**, which may ~~lead-to-discard~~ **prevent** legitimate traffic from being ~~forwarding-~~ **forwarded**. Likewise, invalid ACL entries may lead to forward DDoS traffic.
